developing countries shows that important pre-conditions are not satisfied which will ensure the benefit of privatizing firms operating in markets with natural monopoly characteristics. Then, a long process that creates the necessary conditions to privatize firms in these sectors should be previously carried out.¹

It is interesting to know how important efficiency problems could become when activities with natural monopoly characteristics are privatized. This paper uses contract theory as a way to understand the efficiency consequences of renegotiation in the context of public infrastructure franchising, which is of great importance in developing countries today. There are two theoretical ways to study contracting problems arising when opportunistic parties want to renegotiate their original contract. One way is to assume asymmetric information and the other is to assume symmetric but unverifiable information. In this paper we follow the second approach.²

The main contribution of this paper to the literature in incomplete contracting with symmetric but unverifiable information is the possibility of over-investment in public infrastructure; i.e. "white elephants" are therefore not only consequence of public production but also they may arise under private provision of public infrastructure. Over-investment is not new, however, in the new regulatory economics. Tirole (1986) and Besanko and Spulber (1992) have already found that possibility in an asymmetric information setting.

From the public policy perspective, this paper illustrates the importance of reducing ambiguities (contract incompleteness) in infrastructure franchising. The more ambiguities in contracts, the more likely to departs from optimal allocations of resources. Furthermore, this paper also highlights the importance of strengthening regulatory and judiciary institutions in order to avoid both excessive ambiguities and opportunistic behavior. The worse prepared institutions in the country, the more likely to end up with either the hold-up problem or with "white elephants" in infrastructure.

AND M

A large number of papers has been written during the last two decades regarding the regulation of natural monopolies and procurement.³ Most of the research uses principal-agent models to discuss the government and the monopolist interaction. This literature, however, has minimized the role of incomplete contracts. Contractual incompleteness is particularly useful when studying developing countries, where the regulatory framework is normally ambiguous and both regulatory and judiciary institutions are technically bad prepared to do their duties. Hence, it is fair to assume either the existence of transaction costs or bounded rationality that impede the government to write a complete (contingent) contract before initial investments are fulfilled.⁴ Whatever the explanation to contractual incompleteness is, the parties have to deal with opportunistic behavior arising as a consequence of the non-contracted contingencies.

This paper considers a modified version of the canonical model by Hart and Moore (1988) on symmetric but unverifiable information. They study a procurement relationship between two private parties under incomplete contracting and renegotiation of the price of the good. The main conclusion their paper is the hold-up effect, i.e., the firm under-invests in infrastructure as compared with the

complete contracting situation. Thus, both parties would be better-off if they were able to credibly commit not to renegotiate after sunk investments have been carried out. Other conclusions pertinent to our paper are the following: when the time zero contract is revised, the ex-post surplus is fully appropriated by the party who has more power in the renegotiation game; disputes are not an equilibrium outcome because of the non-verifiability of the initial investments; the parties are severely constrained when setting the price of the good in the original contract; and when only one party's sunk investment matters, optimal (first best) investment levels can be achieved.

Despite being intuitive, the hold-up effect is not robust to changes on basic assumptions of the model. Two important examples are provided by Aghion, et. al. (1994) and Noldeke and Schmidt (1995).⁵ The main problem with those papers is that they assume courts observe more than they typically observe in practice (at least in developing countries). It is precisely the weakness of the judiciary system in developing countries our main argument to justify why we consider Hart and Moore's setting better suitable to analyze infrastructure franchising in developing countries.

We introduce two main changes to Hart and Moore's: (i) a benevolent government is one of the parties in the relationship; and (ii) the variable to be revised in the renegotiation stage is investment in quality, instead of price. Contrary to standard literature, the main conclusions in this paper are that both under-investment and over-investment are feasible subgame perfect Nash equilibrium outcomes; in the case of renegotiation, the ex-post surplus might be shared by the two parties; legal disputes are irrelevant; the government has total freedom to choose its optimal contract at time zero; and the first best investment levels (I^*, q^*) cannot be achieved even when only the firm's investment matters.

The model is presented in the next section. Section III solves the renegotiation game played by the government and the firm after the investment in infrastructure have been sunk and the parties observe the actual state of nature. This section contains one proposition that characterizes the renegotiation process. Section IV presents a solution for the model. Two propositions respectively characterize the firm's investment decision and the optimal time-zero contract. Finally, section V concludes.

II. The Model

Let us first state what we understand for regulated public infrastructure in this paper. They are ports and airports, highways, tunnels, subways, etc. whose common feature is that all of them have both natural monopoly (high sunk investment levels implying decreasing average costs) and public good characteristics (non-rivalry in consumption). Franchising allow the private sector to participate in financing and operating these facilities, but it also gives monopolistic power to the firm. In the more typical infrastructure franchising design, the government gives to a private firm the right to build and, later on, operate the facility for a limited number of

RENEGOTIATING INCOMPLETE CONTRACTS: OVER AND UNDER-INVESTMENT...

the vector of prices to be charged to users of the facility). has to be built (e.g. the level of quality) and how the operation has to be done (e.g. years. A contract signed when the project is granted regulates both how the facility

and no payments are done as compensation for such a decision. aborted in the renegotiation stage, then its economic value is zero for each party and assets are zero for both parties after T. Finally, assume that if the project is fied number of years (T periods). Assume that the economic value of the project what investor obtains the franchise to build and operate the facility by some specito have only one firm for each project. A bidding process for each project decides the construction of infrastructure. Due to scale economies, it is socially preferred Accordingly, consider an economy where the government decides to privatize

without further lost of generality, that the demand for using this facility is deterministic and common knowledge. Therefore, the present value of the revenue for the firm, R, is also deterministic and common knowledge.8 curement relationships. 7 Accordingly, our model assumes contracted prices are change contracted prices, especially in public infrastructure franchising and profixed in the original contract and not ex-post revised. Furthermore, let us suppose, the other party. In the real world, the government may set itself high barriers to verifiable variables (e.g. prices) if and only if such a commitment is credible to Since the government behaves strategically, it will commit not to renegotiate

assume that $\omega \in \Omega$, a finite set. The support of Ω is common knowledge. As we because the true ω is sufficiently complex and of high dimension. Therefore, how the ex-post surplus should be split becontingent investment levels, $l(\omega)$ and $q(\omega)$, the resulting $v(\omega,q)$ and $c(\omega,I)$ could

of the ex-post investment in quality originally contracted ernment and firm have individual incentives to renegotiate q_0 , the specified level will obtain an ex-post surplus equal to $Max \{v(q) + R - c - \phi(q), 0\}$; this surplus will be zero when the government decides to abort the project. ¹³ Therefore, govfirm will obtain ex-post profits equal to $Max / R - c - \phi(q)$, 0}; profits will be zero only if the firm decides to abort the project. On the other hand, for any level of q, if the firm decides to continue and there is no renegotiation, the government it depends on q, which will be invested by the firm before period 2. Thus, for any level of q, if the government accepts the project and there is no renegotiation, the the level of the operational costs. Yet, they do not know how large ν is, because Given the realization of ω and investment I, the government and the firm know Ex-Post Surplus. Let us define first the type of ex-post surplus we consider

> other q if it continues with the project. outcome of the game. On the other hand, it is clear the firm prefers q_L to any $[q_L q_H]$. Whether or not q_0 is smaller than this optimal level affects the final $[q_D q_H]$. Assumptions A.1 and A.3 ensure that \hat{q} belongs to the interior of \hat{q} , which is the unique solution to maximize $\{v(q) + R - c - \phi(q)\}$ subject to $q \in$ If the government wants to continue with the project, its ex-post optimal q is

It is interesting to see what happens when no renegotiation takes place. The project will continue if and only if $[\nu(q_0) + R - c - \phi(q_0) \ge 0]$ and $[R - c - \phi(q_0) \ge 0]$. Otherwise, either the government or the firm would prefer to about the going to obtain zero ex-post surplus. vidually prefer to continue the project (rather than aborting it) when they are project. It is implicit in these inequalities the assumption that both parties indi-

The Bargaining Mechanism. Renegotiation in this context means that the government and the firm exchange a series of messages trying to convince the other party to repudiate the old contract and write a new one. These messages only if the government and the firm have signed it.14 could be read by third parties but they would be a legally valid contract if and

the model to be workable. that this is a strong assumption when one party is the government, but it allows to stop the government (and the firm, of course) agreeing at any time before period 2 to tear-up the old contract and write a new one. It should be recognized Also, let us suppose that messages cannot be forged and that there is nothing

collection of the day. Both parties can send several messages in the same day. Messages sent on day D arrive before parties decide either to invest q or to stop before 2). A message is a letter containing the signature of the sender and it is sent by a reliable "mail" taking I day to arrive. Each party does one collection the project. and one delivery a day. A message delivery the previous day arrives before the be exchanged until day D, where D still belongs to period 1 (so q will be invested Finally, let us describe the message technology used in the revision of q. Time between 1 and 2 can be divided into subperiods (say, days). Messages will

surplus; i.e. \tilde{q} is the minimum q solving $[v(\tilde{q}) + R - c - \phi(\tilde{q}) = 0]$. Two useful definitions that we use in the next proposition are \bar{q} and \bar{q} . Let \bar{q} be the minimum q such that the firm gets zero ex-post payoffs; i.e. \bar{q} solves $[R-c-\phi(\overline{q})=0]$. Let \tilde{q} the minimum q such that government gets zero ex-post

which will apply if no messages are sent between period 1 and day D. Then, conditional on P, q_0 and the realization of ω , the only subgame perfect Nash equilibrium outcome of the renegotiation game, q^2 , can take only five possible sumptions 1 to 4 hold. Let q be the only variable that both parties can credibly renegotiate. Let q_0 be the investment in quality specified by the date-zero contract Proposition 3.1. Consider the model specified in section 2 and suppose as

- i) $q^S = q_0$ if $\hat{q} \ge q_0$ and both parties are better off keeping the time zero contract than stopping the project;
- ii) $q^S = \hat{q}$ if $\hat{q} < q_0$ both parties get a non-negative ex-post surplus at \hat{q} , and no party has all the ex-post power;
- iii) $q^3 = \overline{q}$ if the firm is willing to continue with the project at q_L but not at either q_0 or \hat{q} ; and the government obtains a non-negative ex-post surplus at \overline{q} ;
- iv) $q^2 = \tilde{q}$ if the government is willing to continue with the project at either q_Q or \hat{q} but not at q_U ; and the firm obtains a non-negative ex-post surplus at \tilde{q} ; v) $q^2 = 0$ if either some narry is not william to account the project at either v.)
- v) $q^2 = 0$ if either some party is not willing to continue the project at any $q \ge q_L$ or when one party is willing to continue the project at some $q \ge q_L$ the other party prefers to abort.

Proof. See Appendix

Remark 1. This proposition highlights the importance of the relative ex-post power in allocating property rights over the residual asset of the partnership, the ex-post surplus.

The first case, $q^S = q_0$, arises when the parties' ex-post surplus (the outcome of the renegotiation game) run in opposite directions—what is better for the firm (to reduce q) is worse for the government, and viceversa—and both parties would continue the project as specified by the time-zero contract (see figure 2, below). ¹⁵ The government would accept a new contract if and only if it specifies a higher investment in quality, but such a contract will never be accepted by the firm. Moreover, since the firm is willing to continue with the partnership at q_0 , the government never sends a message asking for replacement of the existing contract for a new one specifying a lower level of investment in quality. The same argument implies that the firm never tries to reduce the contracted quality investment level. In other words, no party has enough power to change the time zero contract.

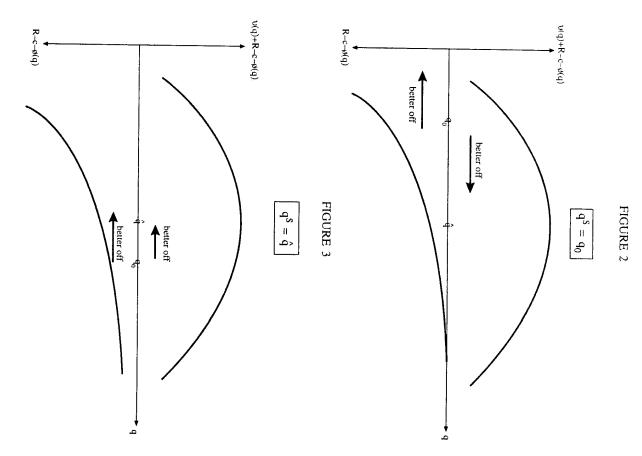

In the second case both parties have equal ex-post power, i.e. either both want to continue with the project or both want to stop it. Nonetheless, both parties are ex-post better-off by reducing the investment in quality, so a new contract tiers-up the previous one and fixes q at \hat{q} (see in figure 3 the case where both parties want to continue at q_0). Notice that the government will not sign any contract specifying any $q < \hat{q}$ because it knows that the firm will accept a take-it-or-leave-it contract specifying \hat{q} in the last day. Any threat by the firm regarding not signing such a contract is not credible because the firm is better-off at \hat{q} than at q_0 .

Weigh

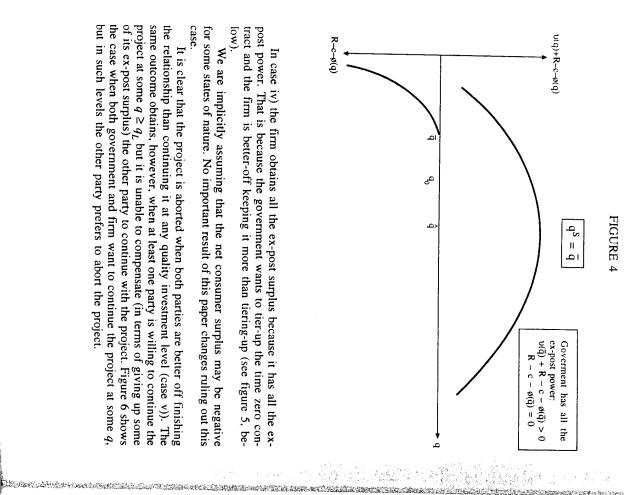

than at q_0 .

Case iii) is more interesting. Here the government has all the ex-post power. So, the outcome of the renegotiation game tells us that the government gets all the ex-post surplus. The firm might send a large amount of messages asking for a new contract with $q < \bar{q}$, but the government would always reject them because it knows that in the last day the firm will accept a take-it-or-leave-it message asking for $q = \bar{q}$ (it should be remember that any party prefers to continue

under-investment and over-investment as feasible outcomes of the game. information. The possibility of revising the original contract allows us to find found in the literature of incomplete contracts with symmetric but unverifiable Remark 2. Propositions 4.1 and 4.2 dramatically change the main result

government's ex-post surplus, at any q, because it increases expected operational in the firm's decision. Changing I away from I^* reduces both the firm and the The first best investment level can rarely be achieved because of externalities

First of all, consistent with Hart and Moore's paper, it may be worthy to the firm to reduce initial investments below I^* . The firm has incentives to underinvest when the benefit of reducing investment in infrastructure $(g(I^*) - g(I'))$, for some $I' < I^*$) is greater than the sum of expected costs in terms of higher operational costs $(E(C_I) - E(C_{I^*}))$ and monetary cost in terms of higher investment in quality of the service (when relevant). This is not the case, however, when either no renegotiation takes place –because in such situation the government sets $q_0 = q^*$ and, therefore, the firm invests I^* —or when revised, $q^5 = \{\bar{q}, 0\}$ in equilibrium. However, under-investment is feasible for any expected situation where this decision is profitable and ex-post renegotiation takes place. This is because both the firm and the government know that the contracted q will change after revised. Therefore, under-investment occurs only if it implies $q^5 = \{\hat{q}, \bar{q}\}$.

Let us provide an example of under-investment. Assume that the firm under-invests because it expects to drive the government to its reservation utility; i.e. with this decision the government is ex-post in a situation of non-voluntary trade at q_0 (see figure 7, below). Then, if the difference $\phi(I^*)-\phi(I')$, for some $I' < I^*$, is greater than $[E(C_{I'})-E(C_{I'})]+[\phi(\tilde{q})-\phi(q_0)]$, then the firm has incentives to invest less than the first best.

This example illustrates the fact that under-investment is more likely to occur when the firm expects ending up in a situation where it obtains all the ex-post power. Thus, shrinking the ex-post pie (summation of ex-post surpluses) is worthy to the firm because it is compensated by obtaining 100% of the shrunk pie.

Regarding over-investment, it is a direct consequence of the possibility to revise the investment plan. Like under-investment, the firm optimally invests when either no renegotiation is expected or the firm's surplus after renegotiation is equal to zero. Therefore, the firm may over-invest for any ex-post $q^S = \{\hat{q}, \tilde{q}\}$.

Let us illustrate the over-investment outcome with an example. Suppose the parties expects an ex-post situation of $\hat{q} < q^*$. Then, setting $q_0 = q^*$ does not change the fact that $q^S = \hat{q}$. Whenever the firm increases I, not only the same expost situation will prevail but also both parties will see a higher ex-post surplus when reducing q to \hat{q} . Hence, if the firm's benefit of over-investing $(E(cI_{f*}) - E(cI_{f*}))$, for some $I' > I^*$ is greater than the monetary cost of increasing I above the optimal level $(\phi(I) - \phi(I^*))$, then the firm is better off over-investing (see figure 8).

This example shows that over-investment is likely to occur when the firm expects to end up in a situation where both parties are willing to reduce the contracted q. Thus, increasing the pie pays more to the firm in such a situation.

It is important to mention that if we only restrict our attention to non-negative net consumer surpluses (\tilde{q} is ruled out as an equilibrium of the renegotiation game), then the only reason to obtain ex-ante inefficiencies in public infrastructure franchising is because both parties expects to share the ex-post surplus after revising the original contract. This result is only feasible because the variable to

be revised, q, attains a maximum in the interior of $[q_L, q_H]$. Therefore, it is consistent with the main conclusion by Bös and Lülfesmann (1996). That is, a benevolent government and a firm always attain the first best when revising prices.

V. Conclusions

This paper presents a model which, departing from Hart and Moore's seminal paper, is capable of dealing with the dynamics of contracts and renegotiation in public infrastructure franchising. One of the main characteristics of this model is that it considers a benevolent government as one of the parties, so the government incorporates the surplus of both consumers and the firm in its objective

function. This allows for a better analysis exclusively concentrated on the cifi-

ciency consequences of incorporating private capital in the infrastructure sector. The second characteristic is that the variable to be revised during renegotiations is the contracted investment plan (investment in quality), so the ex-post surplus of the government attains a maximum in the interior of its feasible set.

The main contribution of this paper to the literature in incomplete contracting with symmetric but unverifiable information is the possibility of over-investment in public infrastructure franchising; i.e. "white elephants" are therefore not only consequence of public production but also they may arise under private provision of public infrastructure. In other words, over-investment may arise in equilibrium even though we assume a rational and benevolent government. Furthermore, as expected, this paper also shows the feasibility of the hold-up effect in this game.

From the public policy perspective, this paper highlights the importance of strengthening regulatory and judiciary institutions in order to avoid both excessive ambiguities in infrastructure franchising and opportunistic behavior by the parties. The more ambiguities in contracts and the worse prepared judiciary and regulatory institutions in the country, the more likely to end up with either the hold-up problem or "white elephants" in infrastructure (i.e. ex-ante inefficiency). Other interesting conclusions in this paper are:

In the case of renegotiation, the ex-post surplus might be shared by the two parties. Such a case may happen when the ex-post optimal investment in quality for the government is above the original contracted level and both parties are willing to continue the project at the time zero contract. Furthermore, in the case of renegotiation when the individual objective function of each party are inversely related, the ex-post surplus is fully obtained by the party which has more power in the renegotiation game.

 Disputes are not a subgame perfect outcome because of non-verifiability of the initial investment, I.

• The government has total freedom to choose its optimal contract at time zero, i.e. the contracted investment in quality is some q_0 belonging to the interval $[q_L,q_H]$. The reason is because investment in quality is not directly related with the individual participation constraint of the firm.

• The first best investment levels (I^*, q^*) cannot be achieved even when only the firm's investment matters.

The model may also be used to explain why non-legal disputes might arise in equilibrium, such as political scandals, mutual allegations of corruption and inefficiencies, public pressures from each party in order to induce a more favorable outcome for itself before completing investments, etc. In spite of being of main importance in developing countries, these more political economy applications of the model are not assessed in this paper, however. We leave them for future research.

This paper has shortcomings. First of all, further research must characterize the equilibria of this incomplete contracting situation. Some non-disjoint alternatives are, for instance, to assume specific probability distributions on ν an c or to restrict the set Ω to a few states of nature.

Regarding the model, it is not fully realistic. Like Hart and Moore's, our paper implicitly assumes that the government is unable to write more sophisticated contracts. Is the government behaving strategically when not designing the renegotiation procedure in the original contract?. An interesting line of research would be to find justifications to our assumption, rather than just assuming the existence of transactions costs at time zero. It is also interesting to know whether our conclusions are robust to introduce endogenous renegotiation in the model.¹⁷

Another point is the assumption that courts are only able to distinguish whether transaction takes place. But, why are courts unable to observe deliveries or intentions of trading?. Why courts cannot randomize?. In this paper we have just assumed that courts, in developing countries, cannot observe more than those in Hart and Moore's paper. Further research ought to assess this point.

Finally, it may be interesting to abandon the benevolent government paradigm. The self-interested paradigm seems to be an adequate assumption to capture the economic problems arising when the government behaves strategically, as it is the case in this paper.¹⁸

Proof to Proposition 3.1

Thanks to the message technology originally proposed by Hart and Moore (1988) –that we are using herein with little changes– there are no legal disputes in stage four. This implies that the renegotiation step can be analyzed as a normal form game (see Hart and Moore, pp. 777).

strategy because firm's payoff continuing with the project are greater than abortmessage sent by the government. But, this is not an equilibrium strategy because the government is better off not signing any message. By the same token, if the any message received from the firm in the case of disputes. If the firm is willing accept the investment in quality done by the firm and neither to sign nor to reveal up all the messages sent by the firm. Later on, the government's strategy is to since ν and c were known asking for tearing up the old contract and offering q^{SPE} equilibrium. Consider the following strategy for the government: do not send any from q^{SPE} to q_0 , a contradiction. ing it $(R - c - \phi(q_0) > 0)$. Therefore, it is worthy for the government to deviate firm wants to abort the project, then q = 0. But, again this is not an equilibrium dispute (q is verifiable), where the government would sign and reveal some of the messages sent by the firm $(q = q^{SPE})$, and the firm would not sign the unique to trade, then $q = q_0$ because any other level would only arise in an eventual from it). At day D the government sends a message to the firm proposing to tier (notice we are analyzing government's deviation from q^{SPE} , not firm's deviation message before than day D. Suppose that the firm sends messages every day is worse off (i.e. $\nu(q^{SPE}) - \varrho(q^{SPE}) < \nu(q_0) - \varrho(q_0)$). Let us show that government has incentives to unilaterally deviates, so q^{SPE} cannot be a subgame perfect Nash changing the quality investment specified in the time zero contract necessarily $\neq q_0$. Since $\hat{q} \geq q_0$, the government (firm) prefers some q above (below) q_0 , then zero contract than stopping the project. Suppose there are at least one subgame perfect Nash equilibrium outcome which implies quality investment equal to q^{SPE} hurts one of the parties. Assume, without lost of generality, that the government Case i), $q^S = q_0$ if $\hat{q} \ge q_0$ and both parties are better off keeping the time

Case ii), $q^S = \hat{q}$ if $\hat{q} < q_0$, both parties get a non-negative ex-post surplus at \hat{q} , and none party has all the ex-post power. Unlike cases where $\hat{q} \ge q_0$, when $\hat{q} < q_0$ both parties have incentives to reduce the quality investment level. The firm prefers to reduce q to q_L and the government only from q to \hat{q} . Thus, any strategy involving $q > \hat{q}$ cannot be a subgame perfect Nash equilibrium because it is strictly dominated by \hat{q} for the two players. The same apply for any $q < \hat{q}$ because they are strictly dominated by \hat{q} for the government. To prove it, consider there exist at least one subgame perfect equilibrium evolving $q^{SPE} \neq \hat{q}$. The government deviates from q^{SPE} to \hat{q} using the following strategy: at day D the government sends its unique message to the firm proposing to tier up both the

de maio participale. Contra Albeit de maio de contra de maio d

investing \hat{q} than nothing. Therefore, the government has incentives to unilaterally deviates from q^{SPE} to \hat{q} , which is a contradiction. token, the firm is not going to abort the project because its payoff are greater nated strategies in the dispute stage as well as we saw in case i). By the same Nash equilibrium, otherwise either government or firm would play strictly domiit decides to invest, then $q = \hat{q}$ because any other q is not a subgame perfect quality investment level equal to \hat{q} . Later on, the government accepts the investfirm (if any) to be revealed in the case of disputes. The firm has two choices. If ment in quality done by the firm and do not sign any message received from the old time zero contract and all the messages sent by the firm, and to fix a new

gies as well as we saw in case i). Therefore, since at \bar{q} the government obtains a non-negative ex-post surplus, it has incentives to unilaterally deviates from q^{SPE} to \overline{q} , which is a contradiction. rium, otherwise either government or firm would play strictly dominated strateto invest, then $q = \overline{q}$ because any other q is not a subgame perfect Nash equilibquality investment level equal to \bar{q} . Later on, the government accepts the investegy: at day D it sends its unique message to the firm proposing to tier-up both messages received by the government, and abort the project (q = 0). Hence, if $q^{SPE} \neq \overline{q}$ then the government must be worse off with q^{SPE} than with $q = \overline{q}$. That is false because the government is better off at \overline{q} using the following strat- \overline{q} is not feasible because the firm has unilateral incentives to deviates in order to not lose money following this strategy: do not send any message during 1 and D, do not sign —and do not reveal to a court in the case of disputes—any of the **surplus at \bar{q}**. Suppose there is at least one subgame perfect Nash equilibrium outcome which entails quality investment equal to $q^{SPE} \neq \bar{q}$, where $\bar{q} = \theta^{-1}(R - c) \in [q_L, q_H]$ by A.3 (i.e. the firm gets zero ex-post surplus). First of all, $q^{SPE} > c$ firm to be revealed in the case of disputes. The firm has two choices. If it decides ment in quality done by the firm and do not sign any message received from the the old time zero contract and all the messages sent by the firm, and to fix a new Case iii), $q^s = \vec{q}$ if the firm is willing to continue with the project at q_L but not at either q_0 or \hat{q} ; and the government obtains a non-negative ex-post

abort the project at q_0 . Hence, the firm offers the government's reservation quality investment, i.e. $q = \tilde{q}$ which is the unique q solving $v(\tilde{q}) + R - c - \phi(\tilde{q}) = 0$. Case iv), $q^S = \tilde{q}$ if the government is willing to continue with the project at either q_0 or \hat{q} but not at q_L ; and the firm obtains a non-negative ex-post surplus at \tilde{q} . The proof here is symmetric to Case iii) except that now the firm has all the power in the revision game because only the government wants to

party is worse off at any $q \ge q_L$, then aborting the project (q = 0) is the only $q \ge q_L$ the other party is better off aborting the project at that level. If some at any $q \ge q_L$ or when one party is willing to continue the project at some subgame perfect Nash equilibrium outcome of the renegotiation game (any $q \ge q_l$ Case v), $q^S = 0$ if either some party is not willing to continue the project

> ship at some $q \ge q_L$ but both $\{v(\overline{q}) + R - c - \phi(\overline{q})\}$ and $\{R - c - \phi(\overline{q})\}$ are negative at that level; i.e. none party has power to bargain because each one is mains is to stop the project. worse off offering to the other party's reservation q than stopping the project ity of ν , c and I impedes the government to go on legal disputes using the time come is no messages are sent by any party, the firm doesn't invest at all, i.e. zero contract. Finally, let us suppose that both parties would continue the partnerabort the project (q = 0), and there are no disputes at the end. The non-verifiabilthan aborting the project. Thus, the only subgame perfect Nash equilibrium outis strictly dominated by q = 0). Suppose, without loss of generality, that the firm wants to abort the project at any $q \ge q_L$. Regardless what $q \in [q_L, q_H]$ the government offers to the firm in a new contract, the firm is worse off accepting the offer Therefore, after deleting strictly dominated strategies the only strategy that re-

Proof to Proposition 4.1

Step 1: Definitions

Let us re-scale the investment such that $I \in (0,1)$. Let I^a be the actual value

of the investment, then define $I = \frac{I^a - I_L}{I_H - I_L}$. The same can be done to re-scale q. Let rename q^S as q_{ij}^S to highlight that the subgame perfect Nash equilibrium

Voluntary trade occurs if and only if $[\nu_i+R-c_j-\phi(q^S_{ij})\geq 0]$ and $[R-c_j-\phi(q^S_{ij})\geq 0]$. $\hat{q}, \ \tilde{q}, \ \tilde{q}, \ 0$

where $\frac{p_j}{p_j''}$ satisfies the monotone likelihood ratio property. Notice that $c(\cdot, I)$. Since $f_j(I)$ satisfies the spanning condition then $f_j(I) = Ip'_j + (1 - I)p''_j$, $\frac{\partial f_j(I)}{\partial r} = p'_j - p''_j$ by definition of $f_j(I)$, so it does not depend on I. Let p'_j and p''_j be the spanning probability distributions over the support of

Define $\Delta f_i = \frac{\partial f_i(I)}{\partial I}$. Likewise, define $\Delta h_i =$ $\frac{\partial h_i(q)}{\partial q}$, which does not depend

from Proposition 1. Define monotonicity by the property $q_{i,j+i}^S \ge q_{ij}^S \ge q_{i+1,j}^S$. This result comes

Finally, let $\sum \equiv \sum_{i=1}^{N} \sum_{j=1}^{J}$

RENEGOTIATING INCOMPLETE CONTRACTS: OVER AND UNDER-INVESTMENT.. 173

Step 2: First Order Stochastic Dominance (FOSD)

in j implies FOSD, then it is enough to show that SC implies f_j to be increasing. Let us show that spanning condition (SC) implies FOSD. Since f_i increasing

$$\frac{\Delta j_j}{f_j(I)} = \frac{p_j + p_j}{lp_j' + (1 - I)p_j''}$$
 dividing both terms by p_j'' :

$$= \frac{p''_{j'} - 1}{I p''_{j'} + (1+I) \frac{p'_{j}}{p''_{j}}}$$

is. 19 but $\frac{p_j'}{p_j''}$ is increasing in j (by the monotone likelihood ratio property), so $\frac{Af_j}{f_{j(l)}}$

Step 3: Existence and Uniqueness of I^S (given q_{ij}^3)

In the complete contracting case (first best), the government's problem is:

$$\max_{I,q} \left\{ \sum f_j(I) h_i(q) [\nu_i + R - c_j - \phi(q)] - \phi(I) \right\}$$

FOC are necessary and sufficient for a unique maximum. By assumptions A.1 to A.3 this objective function is strictly concave, then

$$\begin{split} \frac{\partial \{\cdot\}}{\partial I} &= \sum \Delta f_j h_i(q^*) [\nu_i + R - c_j - \phi(q^*)] - \phi'(I^*) = 0 \\ &\Leftrightarrow A_j(I^*, q^*) = \phi'(I^*) \end{split}$$

$$\begin{split} \frac{\partial \{\cdot\}}{\partial q} &= \sum f_j(I^*) \Delta h_i [\nu_i + R - c_j - \phi(q^*)] - \phi'(q^*) = 0 \\ \Leftrightarrow A_q(I^*, q^*) &= \phi'(q^*) \end{split}$$

In the incomplete contracting case (second best), the firm's problem is:

$M_{i}^{ax}\left\{\sum f_{j}(I)h_{i}(q)[R-c_{j}-\varphi(q_{ij}^{S})]-\varphi(I)\right\}$

sary and sufficient for a maximum. Since $\phi'' > 0$, this objective function is strictly concave, then FOC is neces-

$$\begin{split} \frac{\partial \{\cdot\}}{\partial I} &= \sum \mathcal{A} f_j h_i(q_{ij}^S) [R - c_j - \phi(q_{ij}^S)] - \phi'(I^S) = 0 \\ \Leftrightarrow B_I(I^S, q_{ij}^S) = \phi'(I^S) \end{split} .$$

DEPTH LESS TO BE AND A STATE OF THE STATE OF

exists a unique $I^{S} \in [I_{L}, I_{H}]$ solving $B_{L}(I^{S}, q_{ij}^{S}) = \phi'(I^{S})$ $\phi(I)$ satisfies Inada conditions (A.3), then by the intermediate value theorem there I (by definitions of $f_i(I)$, $\phi(I)$ and FOSD), and non-negative (voluntary trade); and Since B_l is bounded (by A.1 and A.2), continuous and strictly increasing in

Step 4: Second Best Investment Decision (IS)

 A_l changes as q changes. The other one is to know the difference between A_l (l^* , q^*) Two things are important establishing the second best. One is to know how

and $B_I(I^S, q_{ij}^S)$. Let $A_{Iq} \equiv \frac{\partial [A_I]}{\partial_q}$. From the complete information's FOC we have:

$$A_{iq} = \sum \mathcal{A}_i^t \mathcal{\Delta} h_i [\nu_i + R - c_j - \varrho(q^*)] - \varrho'(q^*) \sum \mathcal{A}_j^t h_i(q^*) \underset{<}{>} 0$$

because both terms are positive and their magnitude cannot be a priori inferred.

and q_{ij}^{S} are known by the firm before deciding I^{S} . of q_0 . Remember q_0 is determined by the government in a previous stage, so q_0 Therefore, under and over-investment are likely to occur no matter the level

sufficient but not necessary. example for each alternative. Therefore, the required conditions for each case are To prove the second part of Proposition 2 is enough to show one feasible

vestment is $A_{lq} > 0$. (a) under-investment. Assume $q_0 \le q^*$. A sufficient condition for under-in-

Proof: If $q_0 < q^*$, then, $\sum Af_jh_i(q^S_{ij})\phi(q^S_{ij}) < \sum Af_jh_i(q^*)\phi(q^*)$ because by

Proposition 1 each $q_{ij}^3 \le q_0$ From Planner's FOC: $g'(I^*) = A_f(I^*, q^*)$

but
$$A_{Iq} > 0$$
 implies $> A_I(I^*, q_{ij}^S)$

by firm's FOC: Since $\phi'' > 0$, then $I^S < I^*$. $> B_I(I^S, q_{ij}^S)$ $=A_f(I^S,q_{ij}^S)$

(b) over-investment. It occurs when $q_0 > q^*$, such that

 $\sum \mathcal{A}_j h_i(q_{ij}^S) \phi(q_{ij}^S) > \sum \mathcal{A}_j h_i(q^*) \phi(q^*)$, $A_{iq} < 0$. Same proof as above. This completes the proof.

Proof to Proposition 4.2

Step 1: Definitions and FOSD

tary trade and monotonicity remain the same It is possible to re-scale q such that it belongs to (0,1). Definitions of volum

is (strictly) increasing in *i* by the (strict) monotone likelihood ratio property. Hence, Δh_i satisfies FOSD. Define $\Delta h_i = \frac{\partial h_i(q)}{\partial q}$, which does not depend on q by the definition of h_i , Δh_i

From FOC of the complete contracting case we have: Step 2: Existence and Uniqueness of q_0^S (given I^S and q_{ij}^S)

$$\sum f_j(I^*)\Delta h_i[\nu_i + R - c_j - \phi(q^*)] = \phi'(q^*)$$

$$\Leftrightarrow A_q(I^*, q^*) = \phi'(q^*)$$

In the incomplete contracting case (second best), the government's problem is:

$$\max_{q_0} \left\{ \sum_{j} f_j(I^S) h_i(q_{ij}^S(q_0)) [v_i + R - c_j - \phi(q_{ij}^S(q_0))] - \phi(I^S) \right\}$$

Since $\phi'' > 0$, this objective function is strictly concave, then FOC is necessary and sufficient for a maximum.²⁰

$$\text{FOC: } \sum f_{j}(I^{S}) \Delta h_{i}[\nu_{i} + R - c_{j} - \phi(q_{ij}^{S}(q_{0}))] = \sum_{\{i,j \neq q_{ij}^{S} = q_{0}\}} f_{j}(I^{S}) h_{i}(q_{ij}^{S}(q_{0})) \phi^{i}(q_{0}^{S})$$

or, equivalently

$$D_q(I^S, q_{ij}^S) = \sum_{\{i,j \mid q_{ij}^S = q_0\}} f_j(I^S) h_i(q_{ij}^S(q_0)) \phi^i(q_0^S)$$

where D_q is the first term on FOC

RENEGOTIATING INCOMPLETE CONTRACTS: OVER AND UNDER-INVESTMENT...

Since both terms are bounded (by assumptions A.1 to A.3), continuous and strictly increasing in q (by definitions of $h_i(q)$, $\phi(q)$ and FOSD), and non-negative problem. by the intermediate value theorem there exists a unique $q_0 \in [q_L, q_H]$ solving this (voluntary trade); and $\phi(q)$ satisfies Inada conditions (by assumption A.3), then

Step 3: The Second Best Time Zero Contract

be respectively consistent with: Any subgame perfect Nash equilibrium in the first and the second best has

$$(\#)A_q(I^*,q^*) = \emptyset'(q^*)$$
 and

$$(\#\#)D_q(I^S,q_{ij}^S) = \sum_{(i,j/q_{ij}^S=q_0)} f_j(I^S)h_i(q_{ij}^S(q_0^S))\phi'(q_0^S)$$

Similarly to proof of Proposition 2, the sign of some feasible inequalities are the main importance to identify sufficient (but not necessary) conditions to either $q_0^{S} \ge q^*$ as a best strategy for any I^S . The inequalities here are:

$$\sum f_j(I^S)\Delta h_i \phi'(q_{ij}^S(q_0^S)) \stackrel{>}{\geq} \sum f_j(I^S)\Delta h_i \phi(q^*)$$

and

$$\sum_{\{i,j',q_{ij}^S=q_0\}} f_j(I^s) h_i(q_{ij}^S(q_0^S)) \phi'(q_0^S) \underset{<}{\geq} \phi'(q^*)$$

(a) $q_0^S \ge q^*$ or $q_0^S < q^*$ for $I^S < I^*$. The inequality $\sum f_j(I^S)\Delta h_i \phi'(q_{ij}^S(q_0^S)) < q_0^S$ $q_{ij}^S \le q_0^S$ (it is always true for $q_0^S < q^*$). A sufficient condition to the claim is $\sum f_j(I^S)\Delta h_j \phi(q^*)$ is feasible even though $q_0^S \ge q^*$ because by Proposition 1

$$\sum_{\{i,j'\mid q_{ij}^S=q_0\}} f_j(I^s) h_i(q_{ij}^S(q_0^S)) \phi'(q_0^S) > \phi'(q^*)$$

Proof: $A_q(I^S, q^*) < A_q(I^*, q^*)$ by $I^S < I^*$ and FOSD

by (#):
$$= \phi'(q^*)$$

by suff. condition:
$$<\sum_{\{i,j/q_{ij}^S=q_o\}} f_j(I^S) h_i(q_{ij}^S(q_0^S)) \phi^i(q_0^S)$$

from (##):
$$= D_q(I^S, q_{ij}^S)$$

which is true if and only if $\sum f_j(I^S)\Delta h_i \phi'(q_{ij}^S(q_0^S)) < \sum f_j(I^S)\Delta h_i \phi(q^*)$. Since $q_{ij}^S \leq q_0^S$, the previous inequality holds even though $q_0^S \geq q^*$. Therefore, $q_0^S \geq q^*$. is feasible for any $I^S < I^*$.

(b) $q_0^S > q^*$ for $I^S \ge I^*$. Consider the following weak inequalities $\sum f_j(I^S)\Delta h_i\phi'(q_{ij}^S(q_0^S)) \ge \sum f_j(I^S)\Delta h_i\phi(q^*)$ (which implies $q_0^S > q^*$) and $\sum_{\{i,j',q_0^S=q_0\}} f_j(I^S)h_i(q_{ij}^S(q_0^S))\phi'(q_0^S) \le \phi'(q^*)$. The proof is similar to above.

Therefore, q_0^S need not coincide with q^* . This completes the proof.

Notes

- A general discussion about pros and cons of regulation can be obtained in Khan (1988), Tirole (1988), Vickers and Yarrow (1988), and Armstrong, Cowan and Vickers (1994). To see the experience on privatization and the posterior regulation of utilities in developing countries, see Muñoz (1993) and Bitran and Saavedra (1993).
- ² Mandatory references on this topic are Grossman and Hart (1986). Hart and Moore (1988), Bolton (1990). Chung (1991), Aghion, Dewatripont and Rey (1994), and Noldeke and Schmidt (1995).
- Let me only mention Laffont and Tirole (1993), which contains most of the topics in this area and a large number of references to the relevant literature.
- Transactions costs and bounded rationality are the two more widely accepted explanations for the existence of incomplete contracts in practice; see for instance Williamsom (1975) and (1985), Klein, Crawford and Alchian (1977), Hart and Holmström (1987), More formal justifications to contractual incompleteness are found in Holmström and Milgrom (1991), Spier (1992), Allen and Gale (1992), Anderlini and Felli (1994), and Bernheim and Whinston (1996).
- The implementation theory tells us that efficient investments are attained if the parties are able to design the revision stage in the original contract (e.g. Aghton, et. al. (1994) and Maskin and Tirole (1997)). One problem with the renegotiation design approach is that contracts should be much more sophisticated than they are in practice. For example, when using the revelation principle to obtain efficient investments, Aghton, et. al. assume courts must observe probabilities of trading when quantity is a discrete variable (let say, trade or not trade). Clearly, this is a strong assumption regarding capabilities of judges in practice. Another approach solving the hold-up effect is to assume courts may observe defivery of the good (Noldeke and Schmidt, (1995)). With this very small departure from Hart and Moore's model, the parties are able to implement the first best writing simple option contracts which give the seller the right to deliver and specify payments contingent on whether delivery takes place. Noldeke and Schmidt assume courts may distinguish whether the seller is stopping delivery on its own rather than by the buyer's pressure.
- We indistinctly named to this contract as "original contract", "date-zero contract", or "old contract".

- As a matter of fact, the Chilean government fixes cap prices in real terms (i.e., indexed by inflation) prior to the bidding process. Thus, any renegotiation on those prices is extremely costly because two potential groups of presion—consumers and those firms that did not get the project—become natural watchdogs of the original contract. Furthermore, our assumption also has theoretical support. Bös and Lülfesmann (1996) show that the first best is attained when a benevolent government is the buyer in the Hart and Moore's model.
- We are implicitly assuming here that, above certain minimum level, the demand is inelastic with respect to the quality of the service. This assumption is consistent with the fact that often the quality of the service is not directly observed by consumers (an example, the quality of the air in a tunnel). Quality of the service above such minimum level becomes a "credence good" to users, which affects surplus but not the demand of the service.
- An alternative is to suppose that I cannot be contracted because it is sufficiently complex, such that no contract may describe it at a reasonable cost. In order to maintain our results, we need to re-define the set of all feasible values of I, such that $I \in \Theta$, where Θ is a non-empty, compact and bounded set.
- 10 The investment in quality, q, might be verifiable by courts only if at least one of the parties is willing to do it in an eventual dispute. This assumption avoids a new renegotiation stage in this game.
- Technically, assumption 4 makes sense because $\{v(q)+R-c-\theta(q)\}$ has a maximum on the interior of $[q_L, q_H]$. That is not the case, however, in a procurement model when price is the variable to be revised because in such a case the buyer's payoff function is always decreasing in the difference between p_L (default price if trading) and p_0 (default price if trading). Thus, the first best is attained (when only the firm's investment decision matters) setting (p_L-p_Q) above the Max_{\omega_0} $v(\omega_0)$ because in such a case the firm becomes the only residual claimant of its own investments.
- ¹² We left the bidding process out of the game in order to avoid a more cumbersome model (we focus on post-auction problems).

7 and some Latin American countries). The stronger assumption is necessary to analyze the game in countries with Judiciary System based on Common Law (USA or Britain, for example) where any contract is valid if and only if it has been signed by both parties (e.g. France, Spain, enough to analyze the game played in countries with Judiciary System based on Napoleonic Codes, sent by one party (Hart and Moore's outcome crucially depends on it). Our weaker assumption is An alternative stronger assumption is to assume that it is impossible to publicly record a message

5 Figure 2 illustrates the government and the firm's ex-post surplus as a function of the investment in quality. Notice that these surpluses are never negative, because both parties have the alternative to about the project before undertaken q. Therefore, the vertical axis above zero corresponds to the government's ex-post surplus $(v(q)+R\cdot c\cdot\phi(q))$; and the vertical axis below zero corresponds to the

firm's ex-post profit $(R \cdot c \cdot \phi(q))$. Finally, the horizontal axis corresponds to quality investment q. It is possible to show that it is not an equilibrium strategy to the firm to under-invest when this decision decreases the ex-post investment in quality. This is because the only feasible cases are to end-up at either q = 0 or $q = \overline{q}$. At those levels, the firm obtains zero ex-post gain. Actually, in a very recent paper, Maskin and Tirole (1997) show that the first best may be attained with more sophisticated contracts. They use the same main assumptions of the incomplete ming). It turns out that research in theoretical contract theory should strongly work in explaining contract literature (transaction costs and the possibility that players perform dynamic programwhy agents (including government) prefer simple contracts when complex contracts are at their
